

I'm not robot!

Formats a XML string/file with your desired indentation level. The formatting rules are not configurable but it uses a per-element indentation pattern giving the best readability. Features Many development teams are using more than one IDE because it's a very personal matter, and people always seek what best suits their individual needs. And then there's collaboration, and it sometimes is harder when different sorts of IDEs are involved. One of the most frequently encountered problems is code style, that has to be consistent in the entire project. You may have heard about Eclipse Code Formatter, a quite popular IntelliJ IDEA plugin that lets you, what else, — use Eclipse's code formatter with IntelliJ IDEA. In most cases the plugin is fine, but because it's calling Eclipse API directly from IntelliJ IDEA, there can be problems with processing such actions as refactoring, code generation, etc., so it's not always that helpful. Now things are going to be a bit easier, because IntelliJ IDEA 13 is capable of importing code formatter settings from Eclipse without the use of any plugins. All you need is to export settings from Eclipse (go to Eclipse's Preferences → Java → Code Style → Formatter and export the settings to an XML file via the Export All button.), and then open IntelliJ IDEA Settings → Code Style → Java, click Manage, and import that XML file by simply clicking Import. Currently, IntelliJ IDEA supports the import of the following settings: General Right margin, Formatter on/off tags Indentation Indent size Usage of 'Tab' character Usage of 'Tab' only for leading indentation (Smart Tabs) Indent 'case' branches from 'switch' Indent class members Keep comment at first column Spaces (Java) Before/after comma (as set for Eclipse method declaration parameters) After comma in type arguments Within array initializer braces Within brackets (in array reference) Within parentheses of annotation, 'for', 'if', 'catch', 'while', 'switch', method, empty method, parenthesized expression, method call, type cast, 'synchronized' Before parentheses of 'try', 'for', 'while', 'switch', method, 'if', 'catch', method, method call, 'synchronized'. After type cast Around unary, assignment operators (if it's set for 'before' and 'after' in Eclipse). Before opening brace of: array initializer, 'switch' Before '?' in conditional expression Space before/after ':' in conditional expression Space around binary operators (a single Eclipse setting is mapped to multiple IntelliJ IDEA's settings) Blank lines Around fields and methods Before/after package Before/after imports Before method body Keep blank lines in code (number of empty lines to preserve) Wrapping New line before: closing brace in array initializer, 'else' in 'if' statement, 'finally' and 'catch' in 'try' statement, binary operator (if wrapped) New line after: opening brace in array initializer Special 'else if' treatment (compact 'else if') Keep simple blocks in one line Keep control statements in one line Alignment of: array initializer expressions, arguments in method declarations and calls, field declarations, extends list, assignments, binary expressions, 'throws' clause, resources in 'try'. Brace style for: code blocks, methods and classes JavaDoc Enable JavaDoc formatting Blank lines in JavaDoc Keep in mind that code style settings in IntelliJ IDEA and Eclipse are fundamentally different and can't be mapped one to another with complete accuracy, e.g. you can't tell IntelliJ IDEA to put space after '(' or not to put it before ')'. However, we're constantly working on improving this interoperability, and your feedback with problems and use cases is very appreciated. What's planned for the nearest future: More settings (based on your feedback, tell us what's important for you.) More languages. Working directly with .settings/org.eclipse.jdt.core.prefs, without the need to use the XML export/import. Importing of Conventions (from 'Java Code Style'), e.g. field prefixes. Importing of Code templates and Organize imports settings. Feel free to share your feedback here, or in our discussion forum, or issue tracker. Develop with Pleasure! Usually, issue trackers and IDEs go hand in hand, which is why we've revamped the YouTrack plugin for IntelliJ-based IDEs. The plugin integrates with your favorite JetBrains IDEs — AppCode, CLion, DataGrip, GoLand, IntelliJ IDEA, PhpStorm, PyCharm, Rider, RubyMine, and WebStorm, as well as with Android Studio, and provides you with access to your issues and notifications right from the IDE. We have significantly reworked the plugin's time tracking logic to let you spend your time on your code, not on tracking your time. Read on for more details! A pocket-size tracker Teams that use issue The IntelliJ Platform includes a powerful framework for implementing custom language formatters. In this framework, the plugin specifies the constraints on the whitespaces between different syntax elements. The formatting engine, provided by the IDE, calculates the smallest number of whitespace modifications that need to be performed on the file to make it match the constraints. The process of formatting a file or a file fragment consists of the following main steps: The formatting model builder (FormattingModelBuilder), implemented by the plugin, provides a formatting model (FormattingModel) for the document to be formatted. The formatting model is requested to build the structure of the file as applies to formatting, as a tree of blocks (Block) with an associated indent, wrap, alignment, and spacing settings. The formatting engine calculates the sequence of whitespace characters (spaces, tabs, and/or line breaks) that needs to be placed at every block boundary, based on the plugin's formatting model. The formatting model is requested to insert the calculated whitespace characters at necessary positions in the file. The structure of blocks is usually built so that it mirrors the PSI structure of the file — for example, in Java code, the top-level formatting block covers the entire file. Its children cover individual classes in the file, blocks on the next level cover methods inside classes, etc. The formatter modifies only the characters between blocks, and the tree of blocks must be built so that the bottom-level blocks cover all non-whitespace characters in the file. Otherwise, the formatter may delete the characters between blocks. To better understand how to build the block structure, use PsiViewer and inspect formatting blocks built for an existing language. To invoke PsiViewer with the possibility of inspecting Block Structure, use or To change the default 'block name' taken from class name, return custom Block.getName(). If the formatting operation does not affect the entire file (for example, if the formatter is called to format the pasted block of text), a complete tree of blocks is not built. Rather, only blocks for the text range covered by the formatting operation and their parents are built. For every block, the plugin specifies the following properties: The spacing (Spacing) specifies what spaces or line breaks are inserted between the specified children of the block. The spacing object specifies the minimum and maximum number of spaces that must be placed between the specified child blocks, the minimum number of line breaks to put there, and whether the existing line breaks and blank lines should be preserved. The formatting model can also specify that the formatter may not modify the spacing between the specified blocks. The indent (Indent) specifies how the block is indented relative to its parent block. There are different modes of indenting defined by factory methods in the Indent class. The most commonly used are: the none indent (which means the child block is not indented) the regular indent (the child block is indented by the number of spaces specified in the Tabs and Indents | Indent code style setting) the continuation indent (based on Tabs and Indents | Continuation indent code style setting) If the formatting model does not specify an indent, the "continuation without first" mode is used. This default means that the first block in a sequence of blocks with that type is not indented, and the following blocks are indented with a continuation indent. The wrap (Wrap) specifies whether the content of the block is wrapped to the next line. Wrapping is performed by inserting a line break before the block content. The plugin can specify that a particular block is never wrapped, always wrapped, or wrapped only if it exceeds the right margin. The alignment (Alignment) specifies which blocks should be aligned with each other. If two blocks with the alignment property set to the same object instance are placed in different lines, and if the second block is the first non-whitespace block in its line, the formatter inserts white spaces before the second block, so that it starts from the same column as the first one. For each of these properties, several particular use settings exist, described in the JavaDoc comments for the respective classes. See also SpacingBuilder, which aids in building rule-based configuration. An important special case in using the formatter is the smart indent performed when the user presses the Enter key in a source code file. To determine the indent for the new line, the formatter engine calls the method getChildAttributes() on either the block immediately before the caret or the parent of that block, depending on the return value of the isIncomplete() method for the block before the caret. If the block before the cursor is incomplete (contains elements that the user will probably type but has not yet typed, like a closing parenthesis of the parameter list or the trailing semicolon of a statement), getChildAttributes() is called on the block before the caret; otherwise, it's called on the parent block. Code formatting can be suppressed per region via special comments. Example: Custom Language Support Tutorial: Formatter Sometimes a plugin requires performing non-whitespace characters modifications like reordering methods, changing letter cases, or adding missing braces. The formatting framework provides extension points allowing to achieve these goals. Allows executing additional processing before the actual formatting is performed. For example, it can be used to adjust the formatting range or modify the code by adding, removing, or converting elements like braces, semicolons, quotes, etc. All the introduced changes will be handled by the main formatting step. To register a formatting pre-processor, a plugin has to provide an implementation of PreFormatProcessor and register it in the com.intellij.preFormatProcessor extension point. Example: JsonTrailingCommaRemover removing trailing commas in JSON file! It's similar to the pre-processor but is run after the actual formatting is performed. It can be used for adding, removing, or converting elements like braces, semicolons, quotes, changing letter-cases, etc. To register a formatting post-processor, a plugin has to provide an implementation of PostFormatProcessor and register it in the com.intellij.postFormatProcessor extension point. Example: TrailingCommaPostFormatProcessor inserting trailing commas in Kotlin files. Allows custom languages to provide user-configurable arrangement/grouping rules for element types supported by language plugin. Rules can be refined via modifiers and name: ordering can be applied additionally. Please see Rearranger and related for JavaDoc. To specify the default indent size for the language provided by your plugin, and to allow the user to configure the tab size and indent size, you need to implement the FileTypeIndentOptionsProvider interface and to register the implementation in the com.intellij.fileTypeIndentOptionsProvider extension point. The return value of createIndentOptions() determines the default indent size. Example: Custom Language Support Tutorial: Code Style Settings 2021.3 Register AsyncDocumentFormattingService implementation in extension point com.intellij.formattingService to invoke external formatter instead of IDE's builtin formatter. Example: SHExternalFormatter from Shell Script plugin Last modified: 26 July 2022

XML Formatter. Formatters. XML Formatter. Formats a XML string/file with your desired indentation level. The formatting rules are not configurable but it uses a per-element indentation pattern giving the best readability. Option 1: Copy-paste your XML here. Option 2: Or upload your XML file. File encoding. Text mode. 2017. 2. 16. · IntelliJ Google Style Formatter (Android Studio, WebStorm) 16 Feb 2017 | IDE Formatter Tips. IntelliJ Google Style Formatter . . Google Style . .
